Introduction

H.323 networks have different kinds of configurations and call flows. This document attempts to document most of the security concerns with H.323 networks that involve gatekeepers. This document summarizes the way each feature works and how to troubleshoot it with an explanation to most of the debugs. This document does not address the overall security of Voice over Internet Protocol (VoIP).

This document covers the following features:

- **Intradomain Gateway to Gatekeeper Security** This security is based on H.235, in which H.323 calls are authenticated, authorized, and routed by a gatekeeper. The gatekeeper is considered a known and trusted entity in a sense that the gateway does not authenticate it when the gateway tries to register with it.
- **Interdomain Gatekeeper to Gatekeeper Security** This security covers authenticating and authorizing of H.323 calls between the administrative domains of Internet Telephone Service Providers (ITSPs) using InterZone Clear Token (IZCT). This document covers only the portion where the terminating gatekeeper sends a token in its location confirmation (LCF) message so that it authenticates the answerCall Admission Request (ARQ). Location request (LRQ) validation is not included in this feature. LRQ validation is a feature scheduled for a future Cisco IOS release.

Definitions

Acronym	Definition
ARQ	Admission Request A RAS message sent from an H.323 endpoint to a gatekeeper requesting an admission to establish a call.

ACF	Admission Confirm A RAS message sent from the gatekeeper to the endpoint confirming the acceptance of a call.
ARJ	Admission Rejection A RAS message from the gatekeeper to the endpoint rejecting the admission request.
CAT	Cisco Access Token It is the H.235 Clear Token.
CHAP	Challenge Handshake Authentication Protocol An authentication protocol where a challenge is used.
GCF	Gatekeeper Confirm A RAS message sent from a gatekeeper to the H.323 endpoint confirming the discovery of the gatekeeper.
GRQ	Gatekeeper Request A RAS message sent from an H.323 endpoint to discover the gatekeeper.
H.235	ITU recommendation for security and encryption for H-Series (H.323 and other H.245-based) multimedia terminals.
IZCT	InterZone Clear Token
LRQ	Location Request A RAS message sent from gatekeeper to the next hop gatekeeper or call leg to trace and route the call
RAS	Registration, Admission, and Status A protocol that allows a gatekeeper to perform registration, admission, and status check of the endpoint.
RCF	Registration Confirm A RAS message sent from the gatekeeper to the endpoint confirming the registration.
RRJ	Registration Reject A RAS message sent from the gatekeeper rejecting the registration request.
RRQ	Registration Request A RAS message sent from the endpoint to the gatekeeper requesting to register with it.
RIP	Request In Progress A RAS message sent from a gatekeeper to the sender stating the call is in progress

Intradomain Gateway to Gatekeeper Security

H.323 is an ITU recommendation that addresses securing real-time communication over insecure networks which generally involves two major areas of concern: authentication and privacy. There are two types of authentication, according to H.235:

- Symmetric encryption-based authentication that requires no prior contact between the communicating entities
- Based on the ability to have some prior shared secret (further referenced as subscription based), two forms of subscription-based authentication are provided:
 - password
 - certificate

Time Stamp Passed in the Tokens

A time stamp is used to prevent replay attacks. Therefore, it is needed for a mutually acceptable reference to time (from which to derive time stamps). The amount of acceptable time skew is a local implementation matter.

How Cisco Implements the H.235 Recommendation

Cisco uses a CHAP-like authentication scheme as the basis for its gateway to its gatekeeper H.235 implementation. This allows you to leverage Authentication, Authorization, and Accounting (AAA), using existing functionality to perform the actual authentication. It also means that the gatekeeper is not required to have access to a database of gateway IDs, user account numbers, passwords, and PINs. The scheme is based on H.235, section 10.3.3 and is described as subscription-based password with hashing.

However, instead of using H.225 cryptoTokens, this method uses H.235 clearTokens with fields populated appropriately for use with RADIUS. This token is referred to as the Cisco Access Token. (CAT). You can always perform authentication locally on the gatekeeper instead of using a RADIUS server.

The use of cryptoTokens would require that the gatekeeper either maintains or has some way of acquiring passwords for all of the users and gateways. This is because the token field of the cryptoToken is specified such that the authenticating entity needs the password to generate its own token against which to compare the received one.

So Cisco gatekeepers totally ignore cryptoTokens. However, vocalTek gatekeepers and others who support H.235 section 10.3.3, use the cryptoTokens to authenticate the gateway. Cisco gatekeepers use the CAT to authenticate the gateway. Since the gateway doesn't know what type of gatekeeper he's talking to, it sends both in the Registration Request (RRQ). The authenticationCapability in the Gatekeeper Request (GRQ) are for the cryptoToken and indicate that the MD5 hashing is the authentication mechanism (although the CAT uses MD5 as well).

For detailed information, refer to [Cisco H.323 Gateway Security and Accounting Enhancements](#).

How to Configure the Security Levels

How to Configure the Security Levels

- Endpoint- or Registration-level Security

With Registration Security enabled on the gatekeeper, the gateway is required to include a CAT in all heavyweight RRQ messages. The CAT, in this case, contains information which authenticates the gateway itself to the gatekeeper. The gatekeeper formats a message to a RADIUS server which authenticates the information contained in the token. It responds back to the gatekeeper with either an Access-Accept or Access-Reject, which in turn responds to the gateway with either a Response Confirmation (RCF) or an Response Reject (RRJ).

If a call is then placed from a successfully authenticated gateway, that gateway generates a new CAT upon receipt of an Admission Confirm (ACF) from the gatekeeper using the gateway password. This CAT is identical to the one generated during registration except for the time stamp. It is placed in the outgoing SETUP message. The destination gateway extracts the token from the SETUP message and places it in the destination side ARQ. The gatekeeper uses RADIUS as before to authenticate the originating gateway before sending the destination side ACF. This prevents a non-authenticated endpoint that knows a gateway's address from using it to circumvent the security scheme and accessing the Public Switched Telephone Network (PSTN).

Therefore, in this level, there is no need to include any tokens in the originating ARQs.

To configure the gatekeeper, from the gatekeeper command-line interface (CLI) type `router(config-gk)# [no] security token required-for registration`. The *no* option of the command causes the gatekeeper to no longer check for tokens in Registration, Admission, and Status (RAS) messages.

To configure the gateway, from the gateway CLI, type `router(config-gw)# [no] security password <PASSWORD> level endpoint`. The *no* option of the command causes the gateway to no longer generate tokens for RAS messages.

- Per-call Level Security

Per-call security builds upon registration-level security. In addition to meeting registration security requirements, a gateway is also required to include Access Tokens in all originating side ARQ messages when Per-call security is enabled on the gatekeeper. The token in this case contains information which identifies the user of the gateway to the gatekeeper. This information is obtained using an Interactive Voice Response (IVR) script on the gateway which prompts users to enter their User ID and PIN from the keypad before placing a call.

The CAT contained in the originating ARQ is authenticated by RADIUS the same as described above in Endpoint- or

Registration-level Security. After receiving the ACF, the gateway generates a new CAT using its password and sends it within the H.225 SETUP message to the terminating gateway.

To configure the gatekeeper, from the gatekeeper CLI, type router(config-gk)# **[no] security token required-for all**. The *no* option of the command causes the gatekeeper to no longer check for tokens in RAS messages.

To configure the gateway, from the gateway CLI, type router(config-gw)# **[no] security password <PASSWORD> level per-call**. The *no* option of the command causes the gateway to no longer generate tokens for RAS messages.

- All Level Security

This allows the gateway to include a CAT in all RAS messages needed for registration and for calls, so it is a combination of the above two levels. With this option, the validation of CAT in ARQ messages is based on an the account number and PIN of the user making a call. The validation of the CAT sent in all of the other RAS messages is based on the password configured for the gateway. Therefore, it is similar to the Per-call level.

To configure the gatekeeper, from the gatekeeper CLI, type router(config-gk)# **[no] security token required-for all**. The *no* option of the command causes the gatekeeper to no longer check for tokens in RAS messages.

To configure the gateway, from the gateway CLI, type router(config-gw)# **[no] security password <PASSWORD> level all**. The *no* option of the command causes the gateway to no longer generate tokens for RAS messages.

H.235 Usage on a Per-call Level without IVR

H.235 cannot be used on a per-call level without IVR. If is no IVR to collect an account and PIN, the gateway should send the ARQ without a Clear Token (but with a crypto token). And since the Cisco gatekeeper only accepts Clear Tokens, the call will be rejected by the gatekeeper with a reason of security denial.

The following example shows the **h225 asn1** debugs collected from an originating gateway (OGW) that was not configured for an IVR to collect the account and PIN. You can see that the RRQ message has a Clear Token, but the ARQ does not, and an Admission Rejection (ARJ) message was sent back to the gateway.

Major Issues

The major issues you should be concerned with include:

- Configuration of the gateway and gatekeeper
- RADIUS configuration on the gatekeeper and the RADIUS server
- NTP You must have the same time on all gateways and gatekeepers
- Software failure due to a bug

Debugs and Call Flow for the Different Levels

Since the all level security covers both registration and per-call cases, the lab was set up with that level of security for this exercise. The call flows for the registration part and a normal VoIP call are explained in the configuration below.

Note: The configuration below is not complete, more commands will follow in between the debug outputs. It is designed to show what problem could happen if you do not check all things such as configuration, NTP, and RADIUS. In addition, the gateway was authenticated on the gatekeeper locally so that you can see what values are set for the gateway ID and password. The following configuration was snipped so that only the related configuration is shown.

```

!
interface Ethernet0/0
 ip address 172.16.13.15 255.255.255.224
 half-duplex
 h323-gateway voip interface

!--- This gatekeeper is set as an NTP master

!
end

```

In the example below, the following debugs were turned on:

- debug ras
- debug h225 asn1
- debug radius
- debug aaa authentication
- debug aaa authorization

The first thing that occurs is the gateway sends a GRQ to the gatekeeper and the gatekeeper sends a Gatekeeper Confirm (GCF) to the gateway. The gateway then sends an RRQ and waits for either an RCF or RRJ.

In the above configuration, the gateway is not set for any level of security so that its GRQ would carry no **authenticationCapability** that would be needed for the tokens. But still, the gatekeeper would send back a GCF as shown below.

```

}
authenticationCapability
{
    pwdHash : NULL
}
algorithmOIDs
{
    { 1 2 840 113549 2 5 }
}
}

```

The following explains some of the messages in the GRQ:

- **authenticationCapability** This field only has the value of `pwdHash` and it indicates the MD5 hashing is the authentication mechanism.
 - **algorithmOIDs** The algorithm Object ID. In this case it carries the value `(1 2 840 113549 2 5)` which is the object ID for Message Digest 5 hashing.

(1 2 840 113549 2 5) translates to iso(1) member-body(2) US(840) rsadsi(113549) digestAlgorithm(2) md5(5). Hence Cisco does MD5 password hashing.

Rsadsi stands for RSA data security Inc. RSA Data Security, Inc.'s OSI (Open Systems Interconnection) object identifier is 1.2.840.113549 (0x2a, 0x86, 0x48, 0x86, 0xf7, 0x0d in hex), as registered by the American National Standards Institute (ANSI).

The gatekeeper would again send a GCF as the previous message. The gateway will then send an RRQ with certain fields to describe the tokens it is using to be authenticated. The **asn1 RRQ** message sent is shown in the following example.

```

```

Before discussing the response, we'll explain some of the related fields in the above RRQ message. First, you can see there are two types of tokens: a clear token or what we call Cisco Access Token (CAT), and a crypto token.

As mentioned before, Cisco gatekeepers will ignore the crypto tokens but still the gateway would send both because it does not know to what type of gatekeeper it is talking. And since other vendors might use crypto tokens, the gateway would send both.

The following explains the ClearToken syntax.

- tokenOID The Object ID to identify the token.
- timeStamp The current UTC time of the gateway. seconds since 00:00 1/1/1970 UTC.

It is used as an implied CHAP-Challenge as if it had come from the gatekeeper initially.

- challenge A 16-byte MD5 message digest generated by the gateway using the following fields:

challenge = [random + GW/User Password + timeStamp] MD5 Hash

RADIUS performs the following calculation (since it knows the random number, the gateway password, and the CHAP challenge) to determine what the challenge should be: CHAP Response = [CHAP ID + UserPassword + CHAP Challenge] MD5 Hash

- random A one-byte value used by RADIUS to identify this particular request.

The gateway increments a variable modulo 256 for each authentication request to satisfy this RADIUS requirement.

- generalID The gateway H323-ID or the user account number depending on the level of security and the type of RAS message.

Note: All of these fields are important but we need to give more attention to both the time stamp and the generalID. In our case, the time stamp is **731030839** and the generalID is **gwa-1@cisco.com**.

The cryptoToken in the RRQ contains information about the gateway that generated the token, including the gateway ID (which is the H.323 ID configured on the gateway) and the gateway password.

This field contains one of the cryptoToken types defined for the CryptoH323Token field specified in H.225. Currently, the only type of cryptoToken supported is the cryptoEPPwdHash.

The following fields are contained within the cryptoEPPwdHash field:

- alias The gateway alias, which is the H.323 ID of the gateway
- timestamp The current time stamp

- token The Message Digest 5 (MD5)-encoded PwdCertToken. This field contains the following:

- timestamp The same as the timestamp of the cryptoEPPwdHash
- password The gateway's password
- generalID The same gateway alias as the one included in the cryptoEPPwdHash
- tokenID The object ID

Now we'll view the response from the gatekeeper in the following example.

```
*Mar 2 13:33:15.723: RAS OUTGOING PDU ::=
value RasMessage ::= registrationReject :
{
  requestSeqNum 4
  protocolIdentifier { 0 0 8 2250 0 3 }

00038301 00080067 006B0061 002D0031
*Mar 2 13:33:15.731:
```

As you see above, the RRQ was rejected by the gatekeeper, but why? If you noticed in the configuration of the gateway, there was no Network Time Protocol (NTP) set. The gatekeeper checks the time stamp of the token to see if it is within an acceptable window relative to its own time. Currently this window is +/- 30 seconds around the gatekeeper's UTC time.

A token outside of this window causes the gatekeeper to discard this message. This will prevent replay attacks from someone trying to reuse a snooped token. In practice, all gateways and gatekeepers should use NTP to avoid this time skew problem. The gatekeeper found that the time stamp in the token is within the acceptable window of its time so it did not even bother to check with RADIUS to authenticate the gateway.

The gateway was then configured for NTP pointing to the gatekeeper as the NTP master, so that both the gateway and gatekeeper would have the same time. When this occurred, the gateway sent a new RRQ and this time the gatekeeper replied back to the new RRQ with an RRJ.

The following debugs are from the gatekeeper. Remember that debugs is running to see if the gatekeeper will go to the authentication phase.

```

    protocolIdentifier { 0 0 8 2250 0 3 }
    rejectReason securityDenial : NULL
    gatekeeperIdentifier {"gka-1"}
}

```

As you can see in the example above, after configuring NTP, the gatekeeper still rejects the RRQ. This time, however, it went through the authentication process for that gateway. The gatekeeper rejects the RRQ because the user (here the gateway ID) was not found on the list of valid users on the RADIUS. Remember in the configuration of the gatekeeper, we are authenticating the gateway locally. On the user list you can see gwa-1 but that is not right user since the user in the RRQ is gwa-1@cisco.com. You should be aware of such an issue.

Also, once we configured the username gwa-1@cisco.com password 0 2222 command on the gatekeeper, the gatekeeper confirmed the RRQ and the gateway was registered.

In this lab, another gateway (gwa-2) was registered to the same gatekeeper (gka-1) and we made a call from gwa-1@cisco.com to gwa-2 just to see how the ARQ, ACF, and setup messages will look.

The following debugs collected are from the originating and terminating gateway (gwa-2).

- debug h225 asn1
- debug ras
- debug voip ccapi inout

An explanation of some of the debug messages is included.

Before we print the debugs from the originating/terminating gateway, the following text explains the call flow:

1. Upon receiving a SETUP message from the PSTN, the gateway sends an ARQ to and receives an ACF from the gatekeeper.
2. When the gateway receives the ACF, the gateway generates a CAT using the gateway password, H323-ID alias, and current time. The token is placed in the Call Control Block (CCB).
3. When the gateway sends the SETUP message to the terminating gateway it retrieves the access token from the CCB and places it in the nonStandardParameter field of a clearToken within the SETUP message.
4. The terminating gateway removes the token from the SETUP message, converts it from a nonStandardParameter into a CAT, and places it into the ARQ.
5. The gatekeeper checks the time stamp of the token to see if it is within an acceptable window relative to its own time. Currently this window is +/- 30 seconds around the gatekeeper's UTC time. A token outside of this window causes the gatekeeper to discard this message causing the call to be rejected.
6. If the token is acceptable, the gatekeeper formats a RADIUS Access Request packet, filling in the appropriate attributes to verify a CHAP Challenge and sends it to a RADIUS server.
7. Assuming that the gateway's alias is known at the server, the server locates the password associated with this alias and generates its own CHAP response using the alias, password, and the CHAP Challenge from the gatekeeper. If its CHAP response matches the one received from the gatekeeper the server sends an Access Accept packet to the gatekeeper. If they don't match, or if the gateway's alias is not in the servers database, the server sends an Access Reject packet back to the gatekeeper.
8. The gatekeeper responds to the gateway with an ACF if it received an Access Accept, or an ARJ with cause code **securityDenial** if it received an Access Reject. If the gateway receives an ACF, the call is connected.

The following example shows the debug from the originating gateway.

Note: The **h225 asn1** debugs for the setup is not in this example since it will be the same as seen in the terminating gateway example that follows the originating gateway example.

Gateway IOS Problem

In the same lab, IOS image 12.2(6a) was loaded on the OGW. When a call was made, it was noticed that the OGW still sends a Clear Token based on its password even though the gateway was not configured for IVR to collect the Account/PIN. In addition, the gatekeeper configured for the all level accepted that call. This is documented in the bug ID CSCdw43224.

Security with Alternate Endpoints

As mentioned above, we can provide end-to-end call security with the use of access tokens that is sent in the clearTokens field in the RAS/H225 messages. When enabling such security, the source gateway forwards the access token received from the gatekeeper in an ACF to the destination H.323 endpoint in the H.225 SETUP message. This destination H.323 endpoint then itself forwards the access token received in the SETUP message to the gatekeeper in its admission request. By doing this, it gives the remote gatekeeper the ability to admit calls based on the validity of the access token. The contents of the access token are up to the entity generating it. To minimize security holes and to guard against man-in-the-middle attacks, gatekeepers may encode destination specific information in the access token. This means that when alternateEndpoints are provided in an ACF, the gatekeeper may provide a separate access token for each alternateEndpoint specified.

When first attempting to establish a connection, the Cisco gateway sends the access token it has received in the clearToken field of the ACF with the address in the destCallSignalAddress field. If this attempt is unsuccessful and the Cisco gateway proceeds to attempt connections with an alternate endpoint, it uses the associated access token (if it is available) from the alternateEndpoints list. If the alternateEndpoints list received in the ACF does not include access tokens, but the ACF itself included an access token, the Cisco gateway includes this access

OSP Token Support

Currently the Open Settlement Protocol (OSP) and its tokens are only supported on Cisco gateways; there is no support on the gatekeeper. The gateway recognizes OSP tokens received from a settlement server and inserts them into the Q.931 setup message to a terminating gateway.

Different Levels of Security for each Endpoint or Zone

Currently you cannot configure different levels of security for each endpoint or zone. The security level is for all zones managed by that gatekeeper. A feature request can be opened for such issue.

Interdomain Gatekeeper to Gatekeeper Security

Interdomain gatekeeper to gatekeeper security provides the ability to validate intradomain and interdomain gatekeeper-to-gatekeeper requests on a per-hop basis. This means that the destination gatekeeper will terminate the CAT and generate a new one if the gatekeeper decides to forward the LRQ onwards. If the gatekeeper detects an invalid LRQ signature it responds by sending a Location Reject (LRJ).

Implementing Gatekeeper to Gatekeeper Security

The originating gatekeeper generates an Inter-zone ClearToken (IZCT) when a location request (LRQ) is initiated or an ACF is about to be sent in case of an intra-zone call. This token is traversed through its routing path. Along the path, each gatekeeper updates the destination gatekeeper ID and/or source gatekeeper ID, if necessary, to reflect the zone information. The terminating gatekeeper generates a token with its password, and this token is carried back in the location confirmation (LCF) messages and passed to OGW. The OGW includes this token in the H.225 SETUP message. When the TGW receives the token, it is forwarded in the ARQ answerCall and validated by the terminating gatekeeper (TGK) without any need for a RADIUS server.

The authentication type is based on password with hashing as described in ITU H.235. Specifically, the encryption method is MD5 with password hashing.

The purpose of the IZCT is to know if the LRQ has arrived from a foreign domain, from which zone, from which carrier. It is also used to pass a token to the OGW in the LCF from the TGK. Within the IZCT format, the following information is required:

- srcCarrierID -Source carrier identification
- dstCarrierID - Destination carrier identification
- intCarrierID - Intermediate carrier identification
- srcZone - Source zone
- dstZone - Destination zone
- interzone type
 - INTRA_DOMAIN_CISCO
 - INTER_DOMAIN_CISCO
 - INTRA_DOMAIN_TERM_NOT_CISCO
 - INTER_DOMAIN_ORIG_NOT_CISCO

This feature will work fine without any need for carrier ID from the gateway or a Carrier Sensitive Routing (CSR) server. In such case, the fields about the carrier ID will be empty. The examples below do not include any carrier ID. For a detailed call flow, release and platform support, and configurations, refer to the [Interdomain Gatekeeper Security Enhancement](#) document.

Gatekeeper Configuration

The IZCT feature requires the following configuration on the gatekeeper.

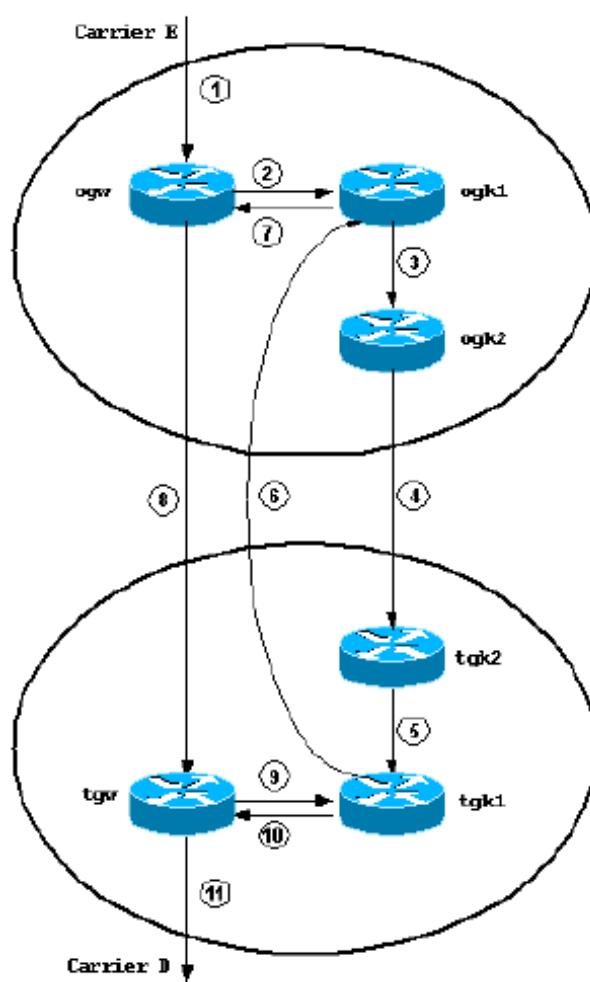

```
Router(gk-config)#[no] security izct password <PASSWORD>
```

The password should be six to eight characters. You will also need to identify which zone is in a foreign domain as follows:

```
Router(config-gk)#zone remote other-gatekeeper-name other-domain-name
other-ip-address
[port-number] [cost cost-value [priority priority-value]] [foreign-domain]
```

IZCT Call Flow

The following diagram shows the IZCT flow.

In the following configuration, the names of the gateways and gatekeepers is the same as those used in the above diagram but with lower case. The call flow is explained after the configuration, with debug explanations.

To explain the IZCT feature and call flow, the first example does not have the intradomain gateway to gatekeeper security. After that, there will be examples where the TGW was not able to generate the IZCT so that the TGK1 would reject the call. This is to show that the feature is working as designed. All of these setups will be based on the topology in the above diagram.

Example 1: Call flow for gatekeeper to gatekeeper security only

The following example shows the related configurations of all gateways and gatekeepers.

- When OGK2 receives the LRQ, it checks the IZCT, and from the configuration it finds that the LRQ should also contain an IZCT. OGK2 then creates a new IZCT by changing the izctSrcZone and izctDstZone to be ogk2 and forwards the LRQ to TGK2. After sending out the LRQ to TGK2, it sends back a RIP message to OGK1.

If the gatekeepers are part of a cluster, the cluster name will be used for the SrcZone or DstZone.

Mar 4 15:31:20.124: RASLib::RASSendLRQ: LRQ (seq# 2048) sent to 172.16.13.16

```

5. TGK2 determines that the LRQ came from a foreign domain. It updates the IZCT's dstZone with its own ID and interZoneType as INTER_DOMAIN_CISCO. It then creates a new CAT and passes the updated IZCT and the LRQ to TGK1.

TGK2 treats the zone from which an LRQ is received as a foreign-domain zone in either of the following two scenarios:

- The TGK2's remote zone list does not contain the zone from which an LRQ is received.
- The TGK2's remote zone list contains the zone from which an LRQ is received and the zone is marked with a foreign-domain flag.

It would then send a RIP message back to OGK1.

```

6. Normally TGK1 updates the IZCT's dstCarrierID to Carrier E, which is determined by the routing process. However, since no carriers are used you will not see that. TGK1 generates a hash token with the IZCT's password, and sends an LCF with the updated IZCT in it to OGK1. This izctHash is used to authenticate the answerCall ARQ that TGK1 receives from the TGW when the later receives the VoIP setup message from OGW.

```

11. The TGW establishes the call toward Carrier D after receiving the ACF.

Example 2: Call failed because TGW was not able to extract the IZCT from the received setup message

The following example is based on the same topology and configuration as Example 1. In this example, the software of the TGW was changed to a version where the IZCT is not supported. In such a case, the TGW is not able to extract the IZCT from the setup message, which causes the TGK1 to reject the call with a disconnect reason of security denial.

This example shows only show the setup message, ARQ, and the ARJ on the TGW since the call flow is the same as Example 1.
